

## Section 1.2

### Solutions and Initial Value Problems

---

---

---

---

---

---

---

### Solutions of Ordinary Differential Equations

A function  $y(t)$  is an explicit solution of an  $n^{\text{th}}$ -order ODE if there exists an interval such that

- 1)  $y(t)$  has  $n$  derivatives for all  $t$  in the interval and
- 2)  $y(t)$  satisfies the ODE for all  $t$  in the interval.

---

---

---

---

---

---

---

### Example 1

Verify that

$$ty' - y = t^2$$

has an explicit solution

$$y(t) = 3t + t^2$$

---

---

---

---

---

---

---

### Example 2

Verify that

$$y(x) = \frac{1}{x}$$

is an explicit solution of

$$xy' + y = 0$$

---

---

---

---

---

---

---

### Implicit Solutions

A relation  $G(x, y) = 0$  is said to be an implicit solution of an  $n^{\text{th}}$ -order ODE if it defines one or more explicit solutions of the ODE.

---

---

---

---

---

---

---

### Example 3

Show that

$$x^2 + y^2 = 4$$

defines an implicit solution of the differential equation

$$\frac{dy}{dx} = -\frac{x}{y}$$

---

---

---

---

---

---

---

### Initial Value Problems

An initial value problem combines an  $n^{\text{th}}$ -order ODE with the  $n$  initial conditions

$$\begin{aligned}y(t_0) &= y_0 \\y'(t_0) &= y_1 \\y''(t_0) &= y_2 \\&\vdots \\y^{(n-1)}(t_0) &= y_{n-1}\end{aligned}$$

A solution to the IVP must satisfy the ODE along with all  $n$  initial conditions.

---

---

---

---

---

---

---

### Example 4

Verify that  $y = (x - 2)^3$  is a solution of the initial value problem

$$\frac{dy}{dx} = 3y^{2/3}, \quad y(2) = 0$$

---

---

---

---

---
