

7 Context Free Grammars

Friday, February 21, 2025

12:16 PM

Why? Because RegEx are not powerful enough.
for programming languages:

$([\]\{\}) \text{ } ?$

BEGIN ... END

Another approach is needed.

• GRAMMARS

DEF: $G = \langle N, T, S, P \rangle$

where: N : set of non-terminal symbols

T : set of terminal symbols Σ

$N \cap T = \emptyset$ N, T are disjoint

$S \in N$: the start symbol

P : a set of "production rules"

rules of the form

$A \rightarrow \alpha$ where $A \in N$

$\alpha \in (N \cup T)^*$

i.e. α is a string made of
terminals and non-terminals.

note α could be the empty string

• In a production

$A \rightarrow \alpha$
head body

• a shorthand:

$A \rightarrow \alpha_1$
 $A \rightarrow \alpha_2$
 $A \rightarrow \alpha_3$ } $A \rightarrow \alpha_1 \mid \alpha_2 \mid \alpha_3$

E.G.

$N = \{A, B, J\}$

$T = \{x, y, z\}$

$S = A$

$P = \left\{ \begin{array}{l} A \rightarrow xBJz \\ A \rightarrow xy \\ B \rightarrow zJy \\ J \rightarrow zzz \\ J \rightarrow Rx \end{array} \right.$

$$S = A$$

$$\begin{cases} J \rightarrow zzz \\ J \rightarrow Bx \end{cases}$$

How does a grammar specifies a language?

Intuition: the production rules are rules to rewrite strings

e.g

$$JxAyz\underline{B} \xrightarrow{B \rightarrow zJy} JxAyz\underline{zJy} \xrightarrow{A \rightarrow xy} J\underline{xy}zzJy$$

DEF:

Sentence:- a string of terminals and non-terminals

Application of a rule R into sentence β

$$R: A \rightarrow \alpha$$

replacing one occurrence of A in β by α

Derivation:- a sequence of sentences each derived from the previous one by the application of a rule.

The language specified by grammar G

$w \in L$ iff there exists a derivation from the start symbol S to w
($w \in T^*$ i.e. w is made only of terminals)

E.G.

$$N = \{A, B, J\}$$

$$T = \{x, y, z\}$$

$$S = A$$

$$P = \begin{cases} A \rightarrow xBJz \\ A \rightarrow xy \\ B \rightarrow zJy \\ J \rightarrow zzz \\ J \rightarrow Bx \end{cases}$$

$$L = \{xy, xzzzzzyzzzz, \dots\}$$

$$A \rightarrow xy$$

$$A \rightarrow x\underline{B}Jz \rightarrow xz\underline{J}y\underline{J}z \rightarrow xz\underline{J}yzzzz \rightarrow xzzzzzyzzzz$$

E.G.

$$N = \{S, A, B, C\}$$

$$T = \{(,), [,], a, b\}$$

$$P = \begin{cases} S \rightarrow A \\ S \rightarrow AaS \end{cases}$$

i.e. we also

$V = \{S, A, B, C\}$
 $T = \{ () [] a b \}$
 $S = S$

$\begin{cases} S \rightarrow AaS \\ A \rightarrow b \mid B \mid C \\ B \rightarrow (S) \\ C \rightarrow [S] \end{cases}$

every time a $($ is introduced, a $)$ is also used.

E.G.

$ba(b)a[(b)]$
 $S \rightarrow AaS \rightarrow baS \rightarrow baAaS \rightarrow baBaS \rightarrow ba(S)aS \rightarrow ba(A)aS \rightarrow$
 $ba(b)aS \rightarrow ba(b)aA \rightarrow ba(b)aC \rightarrow ba(b)a[S] \rightarrow ba(b)a[A] \rightarrow$
 $ba(b)[B] \rightarrow ba(b)[(S)] \rightarrow ba(b)[(A)] \rightarrow ba(b)[(b)]$

MORE ON DERIVATIONS

DEF: **Leftmost Derivation:** a derivation where the leftmost non-terminal is the one re-written

Rightmost Derivation: a derivation where the rightmost non-terminal is the one re-written.

E.G.

$S \rightarrow SAS \mid x \mid y \mid z$
 $A \rightarrow a \mid b$

Prove: $xaybz \in L$

Leftmost

S
 $\underline{S}AS$
 $x\underline{A}S$
 xaS
 $xa\underline{S}AS$
 $xay\underline{A}S$
 $xaybS$
 $xaybz$

Rightmost

S
 SAS
 SAz
 $\underline{S}bz$
 $SASbz$
 $SAybz$
 $Sagbz$
 $xaybz$

DEF: **Parse tree** a tree  representation of a derivation.

DEF: **Parse tree** a tree  representation of a derivation.

- root: the start symbol
- leaf: terminal symbols
- intermediate nodes: non-terminal symbols
- A node's children are the symbols it is rewritten with.

• AMBIGUITY

A grammar is called **ambiguous** when there is a word w in the language that has

- more than one leftmost derivations
- or, more than one rightmost derivations
- or, more than one distinct parse tree:

E.G.

$$S \rightarrow SAS \mid 5 \mid 3 \mid 7$$

$$A \rightarrow + \mid *$$

$$w = 5 * 3 + 7$$

this one is preferred.

E.G. "the dangling 'else'" - Algol '60

$S \rightarrow I \mid S$
 $I \rightarrow \text{if } E \text{ then } S \mid \text{if } E \text{ then } S \text{ else } S$
 $E \rightarrow e$

$w = \text{if } e_1 \text{ then if } e_2 \text{ then } s_1 \text{ else } s_2$

if e_1 then
 if e_2 then s_1
 else s_1

$\begin{matrix} ? \\ \Leftrightarrow \end{matrix}$

if e_1 then
 if e_2 then s_1
 else s_2

Fix: "an else statement is paired with the closest then"

—o—
